Cyber Security : Hardware and Storage

Day 3

Task 5

USB drive not detected: 3 commands

1. **lsusb** lists USB devices the system sees. If the drive isn't listed, the problem is at the hardware, port, cable or VMware passthrough level (in a VM, make sure the USB device is connected to the guest).

2. **sudo dmesg | tail -30** (or dmesg -w while plugging it in) shows kernel messages about the device: detection, driver errors, "device descriptor read" failures, or power problems.

3. **lsblk** (or sudo fdisk -l) shows whether the drive appeared as a block device like /dev/sdb and whether it has partitions. If it shows up here but isn't mounted, the fix is sudo mount /dev/sdb1 /mnt. If it has no partition table or an unknown filesystem, that explains why it isn't auto-mounted.
